

编程语言的设计原理 Design Principles of Programming Languages

Haiyan Zhao, Di Wang 赵海燕,王迪

Peking University, Spring Term 2023

Recap

- Core messages in the previous lecture
 - (Untyped) programming languages are defined by syntax and semantics
 - Syntax is often specified by grammars
 - Inductively vs structural induction
 - Semantics can be specified in three ways, and this book chooses operational semantics expressed as evaluation rules
 - Big step vs small step semantics

Abstract Machines

- An abstract machine consists of:
 - a set of states
 - a transition relation on states, written \rightarrow " $t \rightarrow t'$ " is read as "t evaluates to t' in one step".
- A state records all the information in the abstract machine at a given moment.
 - e.g., an abstract-machine-style description of a conventional microprocessor would include the program counter, the contents of the registers, the contents of main memory, and the machine code program being executed.

Operational semantics for Booleans

Syntax of terms and values

```
true
false
if t then t else t
true
false
```

```
terms
constant true
constant false
conditional
```

```
values
true value
false value
```

Evaluation relation for Booleans

• The evaluation relation $t \to t'$ is the smallest relation closed under the following rules:

$$\begin{array}{c} \text{if true then } t_2 \text{ else } t_3 \longrightarrow t_2 \quad \text{(E-IFTRUE)} \\ \\ \text{if false then } t_2 \text{ else } t_3 \longrightarrow t_3 \quad \text{(E-IFFALSE)} \\ \\ \\ \frac{t_1 \longrightarrow t_1'}{\text{if } t_1 \text{ then } t_2 \text{ else } t_3 \longrightarrow \text{if } t_1' \text{ then } t_2 \text{ else } t_3} \end{array} \tag{E-IF}$$

Evaluation relation for Booleans

Computation rules

if true then
$$t_2$$
 else $t_3 \longrightarrow t_2$ (E-IFTRUE) if false then t_2 else $t_3 \longrightarrow t_3$ (E-IFFALSE)

Congruence rules

$$\frac{\mathtt{t}_1 \longrightarrow \mathtt{t}_1'}{\text{if } \mathtt{t}_1 \text{ then } \mathtt{t}_2 \text{ else } \mathtt{t}_3 \longrightarrow \text{if } \mathtt{t}_1' \text{ then } \mathtt{t}_2 \text{ else } \mathtt{t}_3} \text{(E-IF)}$$

- Computation rules perform "real" computation steps
- Congruence rules determine where computation rules can be applied next

Evaluation relation for Booleans

→ is the smallest two-place relation closed under the following rules:

The notation $t \longrightarrow t'$ is short-hand for $(t, t') \in \longrightarrow$.

If the pair (t, t') is an evaluation relation, then the evaluation statement or judgement $t \to t'$ is said to be derivable

Derivation

 "Justification" for a particular pair of terms that are in the evaluation relation in the form of a tree.

- These trees are called derivation trees (or just derivations).
- The final statement in a derivation is its conclusion.
- We say that the derivation is a witness for its conclusion (or a proof of its conclusion) it records all the reasoning steps that justify the conclusion.

Induction on Derivation

$$\frac{E\text{-IFTRUE}}{s \longrightarrow false} \xrightarrow{E\text{-IF}} E$$

$$t \longrightarrow u$$

$$if t then false else false \longrightarrow if u then false else false$$

- Write proofs about evaluation "by induction on derivation trees."
- Given an arbitrary derivation \mathcal{D} with conclusion $t \to t'$, we assume the desired result for its *immediate sub-derivation* (if any) and proceed by a case analysis of the final evaluation rule used in constructing the derivation tree.

Induction on Derivation

Theorem [Determinacy of one-step evaluation]:

If
$$t \rightarrow t'$$
 and $t \rightarrow t''$, then $t' = t''$.

Proof. By induction on derivation of $t \rightarrow t'$.

If *the last rule* used in the derivation of $t \rightarrow t'$ is E-IfTrue, then t has the form

if true then t2 else t3.

It can be shown that there is only one way to reduce such t.

.

Normal Form

Definition: A term t is in normal form if no evaluation rule applies to it.

Theorem: Every value is in normal form.

- **Theorem**: If *t* is in normal form, then *t* is a *value*.
 - Prove by contradiction (then by structural induction).

Multi-step Evaluation Relation

- Definition: The multi-step evaluation relation →* is the reflexive, transitive closure of one-step evaluation.
- Theorem [Uniqueness of normal forms]:

If $t \to * u$ and $t \to * u'$, where u and u' are both normal forms, then u = u'.

Theorem [Termination of Evaluation]:

For every term t there is some normal form t' such that $t \rightarrow * t'$.

Big-step Evaluation

v ↓ v	(B-VALUE)
$\frac{\texttt{t}_1 \Downarrow \texttt{true} \qquad \texttt{t}_2 \Downarrow \texttt{v}_2}{\texttt{if} \texttt{t}_1 \; \texttt{then} \; \texttt{t}_2 \; \texttt{else} \; \texttt{t}_3 \; \Downarrow \; \texttt{v}_2}$	(B-IFTRUE)
$\frac{\texttt{t}_1 \Downarrow \texttt{false} \qquad \texttt{t}_3 \Downarrow \texttt{v}_3}{\texttt{if} \; \texttt{t}_1 \; \texttt{then} \; \texttt{t}_2 \; \texttt{else} \; \texttt{t}_3 \; \Downarrow \; \texttt{v}_3}$	(B-IFFALSE)
$\frac{t_1 \Downarrow nv_1}{succ t_1 \Downarrow succ nv_1}$	(B-Succ)
$\frac{\mathtt{t}_1 \Downarrow \mathtt{0}}{pred\ \mathtt{t}_1 \Downarrow \mathtt{0}}$	(B-PredZero)
$\frac{\mathtt{t}_1 \Downarrow succ nv_1}{pred \mathtt{t}_1 \Downarrow nv_1}$	(B-PREDSUCC)
$\frac{\texttt{t}_1 \Downarrow \texttt{0}}{\texttt{iszero} \texttt{t}_1 \Downarrow \texttt{true}}$	(B-IszeroZero)
$\frac{\mathtt{t}_1 \Downarrow succ nv_1}{iszero \mathtt{t}_1 \Downarrow false}$	(B-ISZEROSUCC)

Extending Evaluation to Numbers

New syntactic forms

terms: constant zero successor predecessor zero test

values: numeric value

numeric values: zero value successor value

New evaluation rules

$$\frac{\mathtt{t}_1 \to \mathtt{t}_1'}{\mathsf{succ}\ \mathtt{t}_1 \to \mathsf{succ}\ \mathtt{t}_1'}$$

$$\operatorname{pred} 0 \longrightarrow 0$$

pred (succ
$$nv_1$$
) $\rightarrow nv_1$

$$\frac{\mathtt{t}_1 \to \mathtt{t}_1'}{\mathsf{pred}\ \mathtt{t}_1 \to \mathsf{pred}\ \mathtt{t}_1'}$$

$$\texttt{iszero} \; \mathbf{0} \longrightarrow \mathtt{true}$$

iszero (succ
$$nv_1$$
) \rightarrow false (E-IszeroSucc)

$$\frac{\mathtt{t}_1 \to \mathtt{t}_1'}{\mathsf{iszero}\, \mathtt{t}_1 \to \mathsf{iszero}\, \mathtt{t}_1'}$$

$$t \rightarrow t'$$

Stuckness

Definition: A closed term is stuck if it is in normal form but not a value.

- Examples:
 - succ true
 - succ false
 - if zero then true else false

Summary

- How to define syntax?
 - Grammar, Inductively, Inference Rules, Generative
- How to define semantics?
 - Operational, Denotational, Axomatic
- How to define evaluation relation (operational semantics)?
 - Small-step/Big-step evaluation relation
 - Normal form
 - Confluence/termination

Chapter 5: The Untyped Lambda Calculus

What is lambda calculus for?

Basics: Syntax and Operational semantics

Programming in the Lambda Calculus

Formalities (formal definitions)

Why Lambda calculus?

- Suppose we want to describe a function that adds three to any number we pass it.
- We might write

```
plus3 x = succ (succ (succ x))
i.e., plus3 x is succ (succ (succ x))
```

Q: What is plus3 itself?

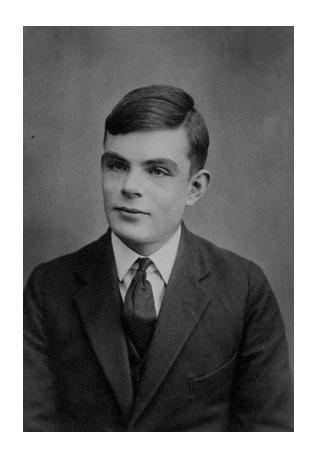

A: plus3 is the function that, given x, yields succ (succ (succ x)).

Story of Turing and Church

Alonzo Church Lambda Calculus *lambda definable* Church' thesis

Alan Turing
Turing Machine
Turing computability

What is Lambda calculus for?

- A core calculus (used by Landin) for
 - capturing the language's essential mechanisms, with a collection of convenient derived forms whose behavior is understood by translating them into the core.
 - modeling programming language, as the foundation of many real-world programming language designs (including ML, Haskell, Scheme, Lisp, ...), and being central to contemporary computer science.

Lambda calculus

- A formal system devised by Alonzo Church in the 1930's as a model for computability
 - all computation is reduced to the basic operations of function abstraction and application.
- A very simple but very powerful language based on pure abstraction
 - Turing complete
 - higher order (functions as data)

Lambda calculus

- Widely used in the specification of programming language features, in language design and implementation, and in the study of type systems
- Importance due to the fact that it can be viewed simultaneously as
 - a simple programming language in which computations can be described and
 - a mathematical object about which rigorous statements can be proved
- can be enriched in a variety of ways

Basics

Syntax Scope

Operational semantics

Syntax

• The *lambda calculus* (or λ -calculus) embodies this kind of function definition and application in the purest possible form.

- Terminology:
 - terms in the pure λ -calculus are often called λ -terms
 - terms of the form λx . t are called λ -abstractions or just abstractions

Syntax

Recall the function

plus3
$$x = succ (succ (succ x))$$

We call write it with λ-terms as:

plus3 =
$$\lambda x$$
. succ (succ (succ x))

Note:

This function exists independent of the name plus3

 $\lambda x.t$ is written "fun $x \rightarrow t$ " in OCaml.

Abstract and Concrete Syntax

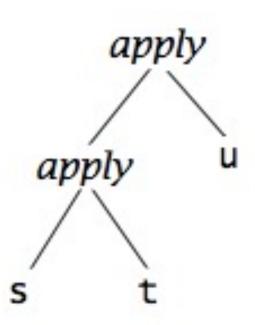

- It is useful to distinguish the syntax of programming languages at two levels of structure:
 - Concrete syntax (or surface syntax) of the language refers to the strings of characters that programmers directly read and write
 - Abstract syntax is a much simpler internal representation of programs as labeled trees (called abstract syntax trees or ASTs)
 - The tree representation renders the structure of terms immediately obvious, making it a natural fit for the complex manipulations involved in both rigorous language definitions (and proofs about them) and the internals of compilers and interpreters.

Abstract Syntax Trees

• (s t) u

Syntactic conventions

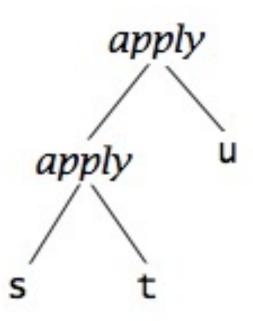

- The λ -calculus provides only one-argument functions, all multi-argument functions must be written in curried style.
- The following conventions make the linear forms of terms easier to read and write:
 - Application associates to the left
 e.g., t u v means (t u) v, not t (u v)
 - Bodies of λ abstractions extend as far to the right as possible e.g., λx . λy . x y means λx . $(\lambda y$. x y), not λx . $(\lambda y$. x) y

Abstract Syntax Trees

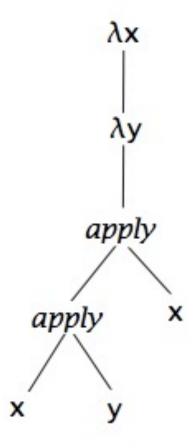

(s t) u (or simply written as s t u)

Abstract Syntax Trees

λx. (λy. ((x y) x))
 (or simply written as λx. λy. x y x)

Scope

- An occurrence of the variable x is said to be bound when it occurs in the body t of an abstraction λx.t, i.e.,
 - the λ -abstraction term $\lambda x.t$ binds the variable x, and the scope of this binding is the body t.
 - $-\lambda x$ is a *binder* whose *scope* is t.
 - a binder can be renamed as necessary
 - so-called: alpha-renaming
 - e.g., $\lambda x.x = \lambda y.y$

Scope

- An occurrence of x is free if it appears in a position where it is not bound by an enclosing abstraction on x.
 - a term with no free variable is said to be closed.
 - closed terms are also called combinators.
- Exercises: Find free variable occurrences from the following terms:
 - x y,
 - $-\lambda x.x$
 - $-\lambda y.xy$
 - $-(\lambda x.x) x$
 - $-(\lambda x.x)(\lambda y.y.x)$
 - $-(\lambda x.x)(\lambda x.x)$
 - $-(\lambda x.(\lambda y.x y)) y$

Operational Semantics

Beta-reduction: the only computation (substitution)

$$(\lambda x. t_{12}) t_2 \rightarrow [x \mapsto t_2] t_{12},$$

- the term obtained by replacing all free occurrences of x in t₁₂ by t₂
- a term of the form $(\lambda x.t)$ v a λ -abstraction applied to a value is called a redex (short for "reducible expression")
- the operation of rewriting a redex according to the above rule is called beta-reduction
- Examples:

$$(\lambda x. x) y y$$

 $(\lambda x. x (\lambda x. x)) (u r) u r (\lambda x. x)$

Operational Semantics

- If the function $\lambda x.t$ is applied to t_2 , we substitute all free occurrences of x in t with t_2 .
 - If the substitution would bring a free variable of t_2 in an expression where this variable occurs bound, we rename the bound variable before performing the substitution.

(
$$\lambda x. t_{12}$$
) $t_2 \rightarrow [x \mapsto t_2]t_{12}$,

Examples:

```
(\lambda x.x) (\lambda x.x) \rightarrow ?

(\lambda x.(\lambda y.x y)) y \rightarrow ?

(\lambda x.(\lambda y.(x (\lambda x.x y)))) y \rightarrow ?
```

Values

$$extstyle v := \lambda extstyle x.t$$

values abstraction value

Evaluation Strategies

- Full beta-reduction
 - any redex may be reduced at any time.
- e. g., $id = \lambda x.x$, consider $(\lambda x.x) ((\lambda x.x) (\lambda z. (\lambda x.x) z))$
 - we can apply full beta reduction to any of the following underlined redexes:

$$\begin{array}{ll} \underline{id} \; (\underline{id} \; (\lambda z. \; \underline{id} \; z)) & \text{outermost} \\ \underline{id} \; (\underline{(id} \; (\lambda z. \; \underline{id} \; z))) & \text{middle} \\ \underline{id} \; (\underline{id} \; (\lambda z. \; \underline{id} \; z)) & \text{innermost} \end{array}$$

Note: lambda calculus is **confluent** under full beta-reduction. Ref. Church-Rosser property.

- The normal order strategy
 - The leftmost, outmost redex is always reduced first.
 - try to reduce always the leftmost expression of a series of applications, and continue until no further reductions are possible
 - the evaluation relation under this strategy is actually a partial function: each term t evaluates in one step to at most one term t'

```
 \frac{\text{id} (\text{id} (\lambda z. \text{id} z))}{\text{id} (\lambda z. \text{id} z)} 
 \rightarrow \lambda z. \underline{\text{id} z}; 
 \rightarrow \lambda z. z 
 \rightarrow
```

- call-by-name strategy
 - a more restrictive normal order strategy, allowing no reduction inside abstraction.

- stop before the last and regard λz . id z as a normal form

- call-by-value strategy
 - only outermost redexes are reduced and
 - where a redex is reduced only when its right-hand side has already been reduced to a value
- value: a term that cannot be reduced any more.

```
id (id (\lambda z. id z))
\rightarrow id (\lambda z. id z)
\rightarrow \lambda z. id z
\rightarrow
```

- call-by-value strategy
 - strict in the sense that the arguments to functions are always
 evaluated, whether or not they are used by the body of the function.
 - reflects standard conventions found in most mainstream languages.

Operational Semantics

Computation rule

$$(\lambda x.t_{12})$$
 $v_2 \longrightarrow [x \mapsto v_2]t_{12}$ (E-APPABS)

Congruence rules

Lambda Calculus

- Once we have
 \(\lambda \)-abstraction and application, we can throw away all
 the other language primitives and still have left a rich and powerful
 programming language.
- Everything is a function:
 - Variables always denote functions
 - Functions always take other functions as parameters
 - The result of a function is always a function

Abstractions over Functions

Consider the
 \(\lambda \)-abstraction

```
g = \lambda f. \ f \ (f \ (succ \ O))
```

- the parameter variable f is used in the function position in the body of g.
- terms like g are called higher-order functions.
- If we apply g to an argument like plus3, the "substitution rule" yields a nontrivial computation:

```
g plus3
= (\lambda f. f (f (succ 0))) (\lambda x. succ (succ (succ x)))
i.e. (\lambda x. succ (succ (succ x)))
((\lambda x. succ (succ (succ x))) (succ 0))
i.e. (\lambda x. succ (succ (succ x)))
(succ (succ (succ (succ 0))))
i.e. (succ (succ (succ (succ (succ 0)))))
```

Programming in the Lambda Calculus

Multiple Arguments
Church Booleans
Pairs
Church Numerals
Recursion

Multiple Arguments

• λ -calculus provides only one-argument functions, all multi-argument functions must be written in curried style.

$$f(x, y) = t$$
 (i.e., $f x y$)

currying

$$(f x) y = t$$

λ-encoding

$$f = \lambda x. (\lambda y. t)$$

Multiple Arguments

- In general, λx. λy. t is a function that, given a value v for x, yields a function that, given a value u for y, yields t with v in place of x and u in place of y.
 - i.e., λx . λy . t is a two-argument function.
- λ -abstraction that does nothing but immediately yields another abstraction is very common in the λ -calculus.

Pairs

Encoding

pair =
$$\lambda f. \lambda s. \lambda b.$$
 b f s
fst = $\lambda p.$ p tru
snd = $\lambda p.$ p fls

Example

Boolean values can be encoded as:

Boolean conditional and operators can be encoded as:

test =
$$\lambda I$$
. λm . λn . $I m n$

	test tru v w	
=	$(\lambda 1. \lambda m. \lambda n. 1 m n) tru v w$	by definition
 →	$(\lambda m. \lambda n. trumn) vw$	reducing the underlined redex
 →	$(\lambda n. tru v n) w$	reducing the underlined redex
 →	truvw	reducing the underlined redex
=	$(\lambda t.\lambda f.t) v w$	by definition
 →	(λf. v) w	reducing the underlined redex
- →	V	reducing the underlined redex

- How to define not?
 - a function that, given a boolean value v, returns fls if v is tru and tru if v is fls.

not = λ b. b fls tru

- Boolean conditional
 - and is a function that, given two boolean values v and w, returns w if v is tru and fls if v is fls.
 - thus and v w yields tru if both v and w are tru, and fls if either v or w is fls.

and operators can be encoded as:

and = λb , λc , b c fls

• How to define or ?

$$or = \lambda a, \lambda b, a tru b$$

Church Numerals

- Encoding Church numerals
 - Basic idea: represent the number n by a function that "repeats some action n times."

```
c_0 = \lambda s. \quad \lambda z. \quad z
c_1 = \lambda s. \quad \lambda z. \quad s \quad z
c_2 = \lambda s. \quad \lambda z. \quad s \quad (s \quad z)
c_3 = \lambda s. \quad \lambda z. \quad s \quad (s \quad (s \quad z))
```

— each number n is represented by a term c_n taking two arguments, s and z (for "successor" and "zero"), and applies s, n times, to z.

Functions on Church Numerals

Successor

suc =
$$\lambda n. \lambda s. \lambda z. s (n s z)$$
;

addition

plus =
$$\lambda m. \lambda n. \lambda s. \lambda z. m s (n s z);$$

Multiplication

times =
$$\lambda m. \lambda n. m$$
 (plus n) c0;

Zero test

iszro =
$$\lambda$$
m. m (λ x. fls) tru

Church Numerals

- Can you define minus?
 - Suppose we have pred, can you define minus?
 - $\lambda m. \lambda n. n pred m$
- Can you define pred?
 - $-\lambda n. \lambda s. \lambda z. n (\lambda g. \lambda h. h (g s)) (\lambda u. z) (\lambda u. u)$
 - $-(\lambda u.z)$ -- a wrapped zero
 - $-(\lambda u.u)$ the last application to be skipped
 - $-(\lambda g.\lambda h.h(gs))$ -- apply h if it is the last application, otherwise apply g
 - Try n = 0, 1, 2 to see the effect

Church Numerals

- predecessor
 - -zz = pair c0 c0
 - $-ss = \lambda p. pair (snd p) (scc (snd p))$
 - $\text{ prd} = \lambda \text{m. fst (m ss zz)}$

Normal forms

- Recall
 - A normal form is a term that cannot take an evaluation step.
 - A stuck term is a normal form that is not a value.

- Are there any stuck terms in the pure λ -calculus?
- Does every term evaluate to a normal form?

Divergence

omega =
$$(\lambda x. x x) (\lambda x. x x)$$

- Note that omega evaluates in one step to itself!
 - evaluation of omega never reaches a normal form: it diverges.

Terms with no normal form are said to diverge.

Divergent computation does not seem very useful in itself. However,
 there are variants of omega that are very useful...

Recursion

Fixed-point combinator

fix =
$$\lambda f. (\lambda x. f (\lambda y. x x y)) (\lambda x. f (\lambda y. x x y));$$

$$fix f = f(\lambda y. (fix f) y)$$

Recursion

Basic Idea:

A *recursive* definition:

$$g = \lambda f$$
. f > h = fix g

Recursion

Example:

```
fac = \lambda n. if eq n c0
          then c1
          else times n (fac (pred n)
    g = \lambda f \cdot \lambda n. if eq n c0
                   then c1
                   else times n (f (pred n)
    fac = fix g
Exercise: Check that fac c3 \rightarrow c6.
```

Design Principles of Programming Language, Spring 2023

Y Combinator

$$Y = \lambda f. (\lambda x. f(x x)) (\lambda x. f(x x))$$

fix =
$$\lambda f$$
. (λx . f (λy . x x y)) (λx . f (λy . x x y))

Why fix is used instead of Y?

Y Combinator

$$Y = \frac{(\lambda x. f (x x)) (\lambda x. f (x x))}{\longrightarrow}$$

$$f ((\lambda x. f (x x)) (\lambda x. f (x x)))$$

$$\longrightarrow$$

$$f (f ((\lambda x. f (x x)) (\lambda x. f (x x))))$$

$$\longrightarrow$$

$$f (f (f ((\lambda x. f (x x)) (\lambda x. f (x x)))))$$

$$\longrightarrow$$

$$\cdots$$

$$\cdots$$

Answer

fix =
$$\lambda f. (\lambda x. f (\lambda y. x x y)) (\lambda x. f (\lambda y. x x y))$$

- Assuming call-by-value
 - (x x) is not a value
 - while $(\lambda y. x x y)$ is a value
 - Y will diverge for any f

Formalities (Formal Definitions)

Syntax (free variables)

Substitution

Operational Semantics

Syntax

Definition [Terms]:

Let \mathcal{V} be a *countable set* of variable names.

The set of terms is the smallest set T such that

- 1. $x \in \mathcal{T}$ for every $x \in \mathcal{V}$;
- 2. if $t_1 \in \mathcal{T}$ and $x \in \mathcal{V}$, then $\lambda x.t_1 \in \mathcal{T}$;
- 3. if $t_1 \in \mathcal{T}$ and $t_2 \in \mathcal{T}$, then $t_1 t_2 \in \mathcal{T}$.
- **Definition:** Free Variables of term t, written as FV(t):

$$FV(x) = \{x\}$$

$$FV(\lambda x.t_1) = FV(t_1) \setminus \{x\}$$

$$FV(t_1 t_2) = FV(t_1) \cup FV(t_2)$$

Substitution

$$[x \mapsto s]x = s$$

$$[x \mapsto s]y = y \qquad \text{if } y \neq x$$

$$[x \mapsto s](\lambda y.t_1) = \lambda y. [x \mapsto s]t_1 \qquad \text{if } y \neq x \text{ and } y \notin FV(s)$$

$$[x \mapsto s](t_1 t_2) = [x \mapsto s]t_1 [x \mapsto s]t_2$$

Alpha-conversion: Terms that differ only in the names of bound variables are interchangeable in all contexts.

Example:

$$[x \mapsto y z] (\lambda y. x y)$$
= $[x \mapsto y z] (\lambda w. x w)$
= $\lambda w. y z w$

Operational Semantics

Syntax

t ::=

X

 $\lambda x.t$

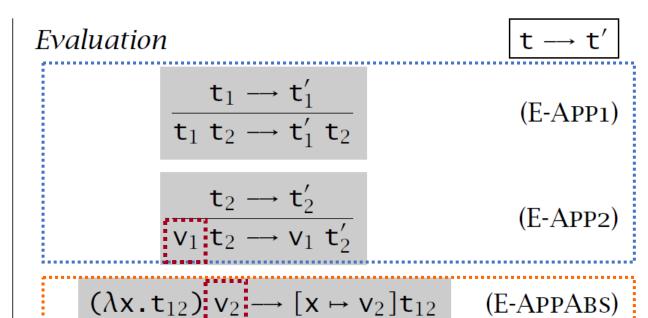

t t

V ::=

 $\lambda x.t$

terms: variable abstraction application

values: abstraction value

Summary

- What is lambda calculus for?
 - A core calculus for capturing language essential mechanisms
 - Simple but powerful
- Syntax
 - Function definition + function application
 - Binder, scope, free variables
- Operational semantics
 - Substitution
 - Evaluation strategies: normal order, call-by-name, call-by-value

Homework

- Read through and understand Chapter 5.
- Do exercise 5.2.7, 5.3.6 in Chapter 5.
 - 5.2.7 EXERCISE [★★]: Write a function equal that tests two numbers for equality and returns a Church boolean. For example,

```
equal c_3 c_3;
```

► (λt. λf. t)

equal c_3 c_2 ;

• (λt. λf. f)

5.3.6 EXERCISE [★★]: Adapt these rules to describe the other three strategies for evaluation—full beta-reduction, normal-order, and lazy evaluation. □
